# 1.INTRODUCTION

## 1.1 Overview

Over the decade there has been rapid growth in wind generation of electricity. In the wind energy industry, it is of great importance to develop models that accurately forecast the power output of a wind turbine, as such predictions are used for wind farm location assessment, monitoring, and preventive maintenance. The energy output of a wind farm is highly dependent on the weather conditions present at its site. If the output can be predicted more accurately, energy suppliers can coordinate the collaborative production of different energy sources more efficiently to avoid costly overproduction. The goal of this project is to draw an insight from the given dataset and then use a RNN (Recurrent Neural Network) algorithm by data preprocessing and embedding to the model. Recurrent Neural Network remembers the past and its decisions are influenced by what it has learnt from the past. This method is believed to bring more information for predicting the energy output of wind turbine and in result have better determination of wind generation output based on weather condition. Thus wind power forecasting plays a key role in dealing with the challenges of balancing supply and demand in any electricity system, given the uncertainty associated with the wind farm power output. Hence the time series model is developed to predict the power output in wind farm based on weather condition.

## 1.2 Purpose

The capacity of wind energy production has been substantially increased during the last years. However, levels of production of wind energy are hard to predict as they rely on potentially unstable weather conditions present at the wind farm. In particular, wind speed is crucial for energy production based on wind, and it may vary drastically over time. So the purpose of this project is to give accurate predictions and to avoid overproduction by coordinating the collaborative production of traditional power plants and weather-dependent energy sources.

## **2.LITERATURE SURVEY**

### **2.1 Existing problem**

The supervisory control and data acquisition (SCADA) data to model the wind turbine power curve (WTPC) existing model are:

- Kusiak, Zheng, and Song have shown how wind speed data may be used to predict the power output of a wind farm based on time-series prediction modeling. Neural networks are a very popular learning approach for wind power forecasting based on given time series. They provide an implicit model of the function that maps the given weather data to an energy output.
- Jursa and Rohrig have used particle swarm optimization and differential evolution to minimize the prediction error of neural networks for short-term windpower forecasting.
- Kramer and Gieseke used support vector regression for short term energy forecast and kernel methods and neural networks to analyze wind energy time series .

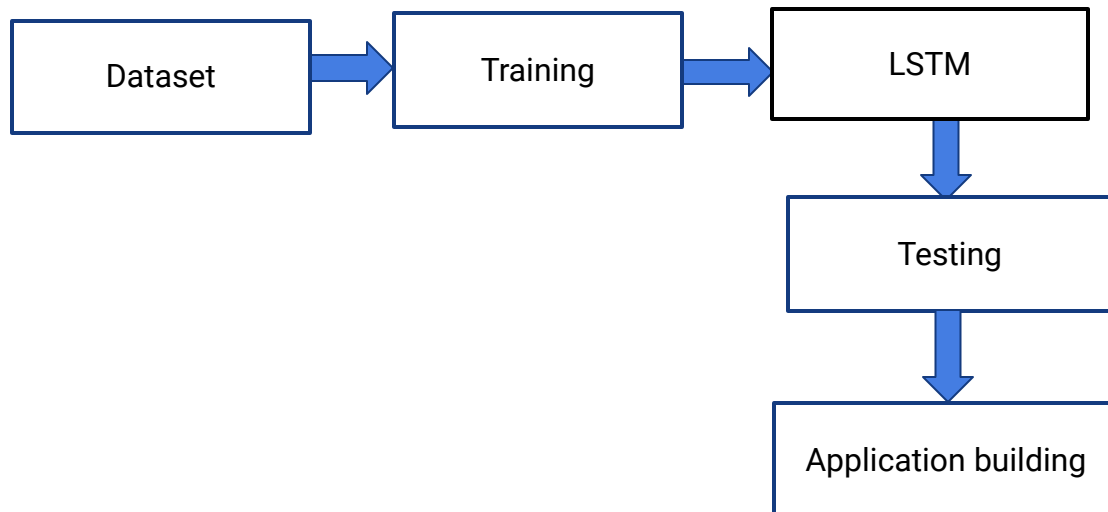

### **2.2 Proposed solution**

The aim of this project is to use the SCADA data to check the feasibility of wind energy prediction and to identify the minimal subset of driving weather features that are significantly related to the wind energy output of the wind farm. At the modeling stage, we reduce the training data to the set of selected inputs using RNN algorithm to obtain models and also by plotting the graph, and model ensembles for predicting energy output. This time series model is developed to predict the future power output in wind farm based on weather condition and to give accurate prediction using flask API .

### 3.THEORITICAL ANALYSIS

In the statistical approach a vast amount of data is analyzed and meteorological processes are not explicitly represented. The link between historical power production and weather is determined and then used to forecast the future power output. Unlike physical methods, statistical methods involve only one-step to convert the input variables into power output. As soon as weather and energy data from different sources were put in an appropriate input-output form, we were able to apply a standard data-driven modeling approach to them. A good approach employs iterations among three stages: Data Collection/Reduction, Model Development, and Model Analysis and Variable Selection. In hard problems, many iterations are required to identify a subspace of minimal dimensionality where models of appropriate accuracy and complexity tradeoffs can be built. RNN converts the independent activations into dependent activations by providing the same weights and biases to all the layers, thus reducing the complexity of increasing parameters and memorizing each previous outputs by giving each output as input to the next hidden layer. Hence these three layers can be joined together such that the weights and bias of all the hidden layers is the same, into a single recurrent layer. The neural network model is found to possess better performance than the regression model for turbine power curve estimation under complicated influence factors.

#### 3.1 Block diagram

## **3.2 Hardware/Software designing**

### **Hardware requirement:**

1. Operating system: Windows 10
2. Hard disk: 500 GB
3. RAM: 2GB

### **Software requirement:**

1. Anaconda navigator
2. Jupyter notebook
3. Spyder

## **4. EXPERIMENTAL INVESTIGATION:**

### **4.1 Dataset Collection:**

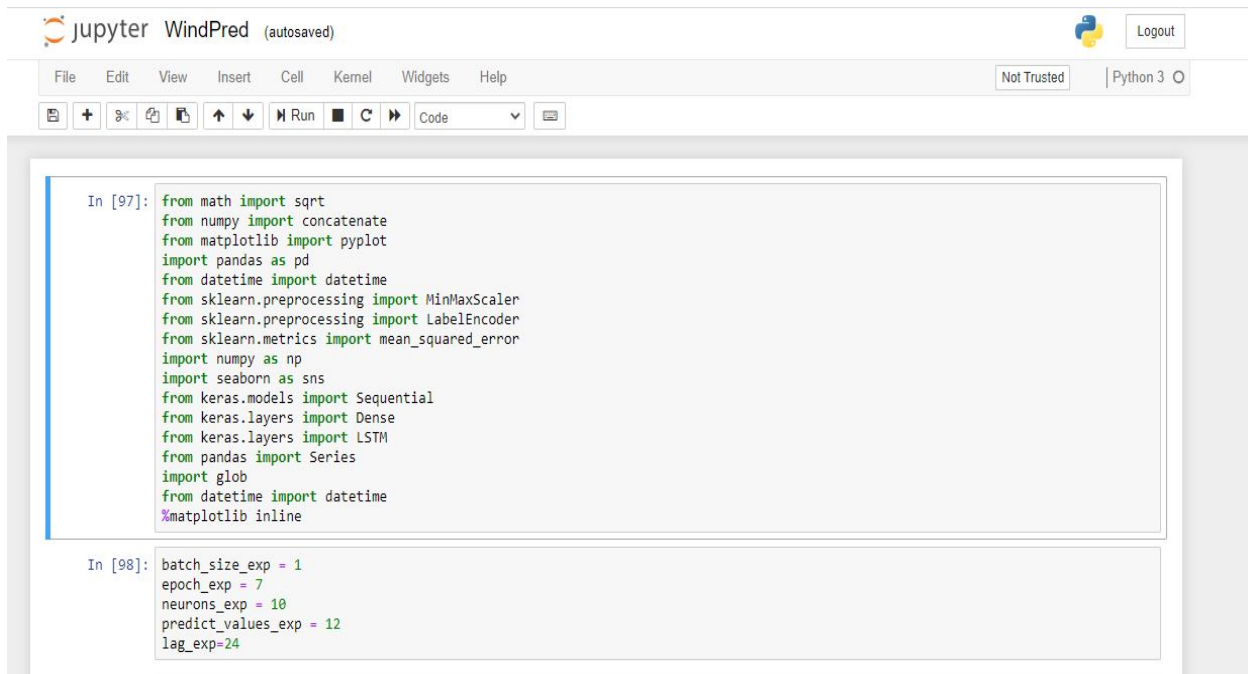

- The dataset was downloaded from the kaggle repository.  
<https://www.kaggle.com/berkerisen/wind-turbine-scada-dataset>
- The dataset is in the format of .csv type file.
- It has 5 columns, We are using Theoretical Power column for building the model.

Figure 4.1- Dataset

## 4.2 Importing Libraries:

- Keras is an open source neural-network library written in Python.
- numpy is used for performing numerical operations in Python.
- sklearn library provides many supervised and unsupervised learning algorithms and also used for preprocessing techniques like feature scaling.
- pandas library is used for data analysis.
- seaborn is used for data visualization.

The image shows a Jupyter Notebook interface with the title 'WindPred (autosaved)'. The top bar includes a 'Logout' button and a 'Python 3' indicator. The menu bar contains 'File', 'Edit', 'View', 'Insert', 'Cell', 'Kernel', 'Widgets', and 'Help'. Below the menu is a toolbar with icons for file operations, running, and code execution. The notebook contains two code cells. The first cell, labeled 'In [97]:', imports various libraries including math, numpy, matplotlib, pandas, datetime, sklearn, keras, and glob. The second cell, labeled 'In [98]:', defines several variables: batch\_size\_exp, epoch\_exp, neurons\_exp, predict\_values\_exp, and lag\_exp.

```
In [97]: from math import sqrt
from numpy import concatenate
from matplotlib import pyplot
import pandas as pd
from datetime import datetime
from sklearn.preprocessing import MinMaxScaler
from sklearn.preprocessing import LabelEncoder
from sklearn.metrics import mean_squared_error
import numpy as np
import seaborn as sns
from keras.models import Sequential
from keras.layers import Dense
from keras.layers import LSTM
from pandas import Series
import glob
from datetime import datetime
%matplotlib inline

In [98]: batch_size_exp = 1
epoch_exp = 7
neurons_exp = 10
predict_values_exp = 12
lag_exp=24
```

Figure 4.2- Importing Libraries

### 4.3 Model Building:

- Define the methods for ranging the inputs and outputs of a model.
- Apply the scaling functions on data.
- Initialize the model.
- Add the RNN(LSTM) layer.
- Add the Dense layer and give the output units.
- Compile the model by giving the loss as "mse".
- Fit the model.
- Predict the output by random prediction.
- Save the model .

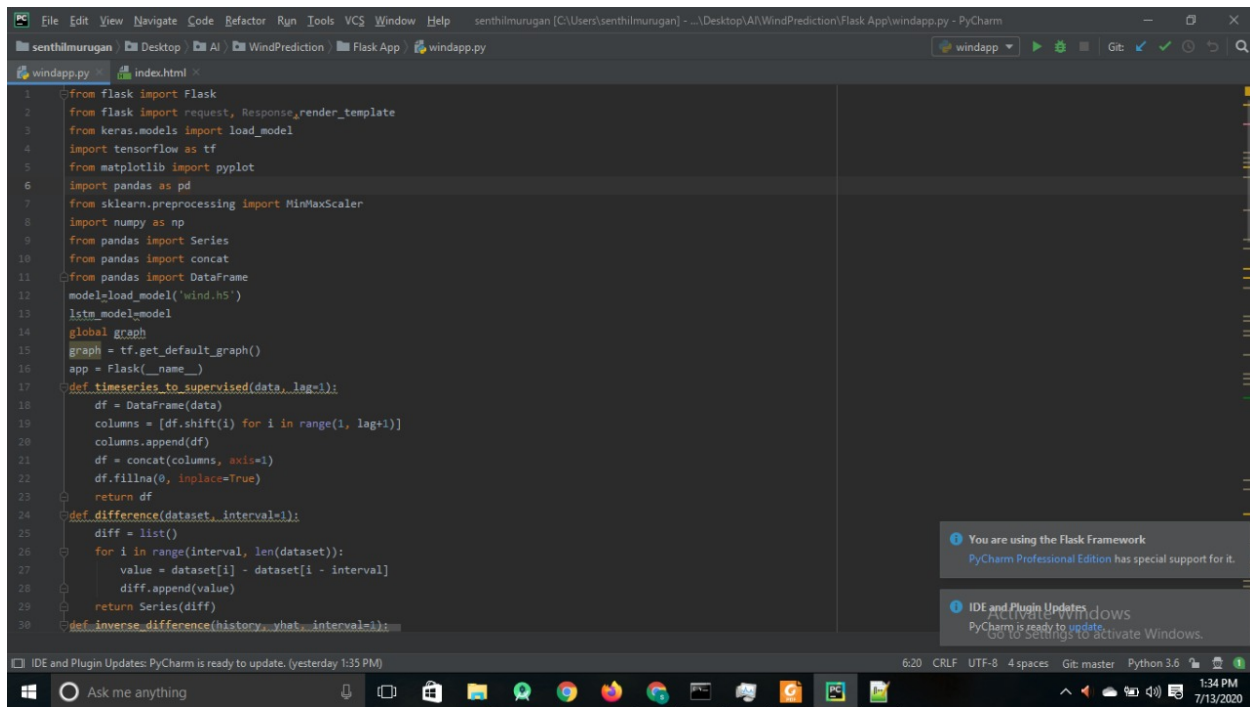

## 4.4 Build an UI:

To create interactive webpage the Web technologies like HTML, CSS, JavaScript, PHP and JQuery are used. HTML - HTML is the standard markup language for creating Web pages. It describes the structure of a Web page. It consists of a series of elements. They tell the browser how to display the content. CSS - CSS stands for Cascading Style Sheets. It describes how HTML elements are to be displayed on screen, paper, or in other media. It can control the layout of multiple web pages all at once. Javascript - Javascript is the Programming language of HTML and the web. PHP - PHP is used for interaction with the files and for prediction call. JQuery - jQuery is a lightweight, "write less, do more", JavaScript library. The purpose of jQuery is to make it much easier to use JavaScript on your website.

Importing flask module in the project is mandatory. An object of Flask class is our WSGI application. Flask constructor takes the name of current module (`__name__`) as argument. Pickle library to load the model file.

Open anaconda prompt from start menu. Navigate to the folder where your app.py resides. Now type "python app.py" command. It will show the local host where your app is running. Navigate to the localhost where you can view your web page. Enter the images and see the prediction on web page.

Figure 6.4 - Result

## **7. ADVANTAGES AND DISADVANTAGES**

### **Advantages of Recurrent Neural Network**

- An RNN remembers each and every information through time. It is useful in time series prediction only because of the feature to remember previous inputs as well. This is called Long Short Term Memory.
- Recurrent neural network are even used with convolutional layers to extend the effective pixel neighborhood.
- Possibility of processing input of any length.
- Model size not increasing with size of input.
- Computation takes into account historical information.
- Weights are shared across time.

### **Disadvantages of Recurrent Neural Network**

- Gradient vanishing and exploding problems.
- Training an RNN is a very difficult task.
- It cannot process very long sequences if using tanh or relu as an activation function.
- Computation being slow.
- Difficulty of accessing information from a long time ago.
- Cannot consider future input for the current state.

## 8. APPLICATIONS

RNNs are widely used in the following domains/ applications:

- Prediction problems
- Language Modelling and Generating Text
- Machine Translation
- Speech Recognition
- Generating Image Descriptions
- Video Tagging
- Text Summarization
- Call Center Analysis
- Face detection, OCR Applications as Image Recognition
- Other applications like Music composition

### Text Generation

Generating text with recurrent neural networks is probably the most straightforward way of applying RNN in the context of the business operation .Text generation is valuable as a means for streamlining the workflow and minimizing the routine.Natural language generation relies on Recurrent Neural Networks predictive algorithms. Since the language is sequentially organized with grammar and bound into cohesion with semantics - it is relatively easy to train a model to produce generic text documents for multiple purposes.

## **Text Summarization**

Text summarization is the process involves condensing the original text into a distillation of critical points and its subsequent reiteration into a cohesive summary. Summarization is used in project management to quickly onboard new members and keep an eye on the progress in general. This approach is also used to create news digests and streamline news article production pipeline.

## **Report Generation**

Report Generation in this case, text generation serves as a form of data visualization. Except, instead of turning data into bars and charts and graphs, the text is transformed into a formatted document with template sentences covering key points. Here's an example of this kind of report: "There were 100 visitors on site during 24 hour period, which is two visitors more compared with the previous 24 hour period. Twenty-five visitors came from Facebook, 10 of which bounced off instantly, while the other 15 made from 5 to 20 clicks on the following page".

## **Speech-to-text application**

Sound is another medium where content marketing can thrive. Due to a variety of reasons, not every user has time to read a blog post from start to finish, but they are likely to listen to it. However, recording read-outs with voice actors can be a bit too much on the budget. Hopefully, modern speech-to-text applications are capable of doing a serviceable and cost-effective job without calling much attention to its mechanistic nature. Such claims have sample banks with phonetic segments performed in different languages that are arranged in the form of the input text. Blogging platforms like Medium are currently trying out these features, and many separate services provide speech-to-text transformations, such as SpeechNote and VoiceNotebook.

## **Video tagging**

RNNs can be used for video search where we can do image description of a video divided into numerous frames.

## **Face detection, OCR Applications as Image Recognition**

Image recognition is one of the major applications of computer vision. It is also one of the most accessible form of RNN to explain. In its core, the algorithm is designed to consider one unit of image as input and produce the description of the image in the form of multiple groups of output .

The image recognition framework includes:

1. Convolutional neural network that processes the image and recognizes the features of the pictures,
2. Recurrent neural networks that makes use of the known features to make sense of the image and put together a proper description of the input image.

## **Predictive Analytics**

In a way, recurrent neural network stock prediction is one of the purest representations of RNN applications. It is all tweaking numbers to understand what the next figure might be. The critical term is time series prediction, which is a representation of the number figure fluctuation or transformation over time. Apps like Stock Market Sensei use this approach. The transformation includes a specific criterion that affected the changes (for example, the connection of the special price to the other expenses). The combination of the elements above is then taken into consideration upon calculation of the predictions. The predictions itself range by probability from the most to the least possible from the available data. As a result, the stock market trader gets more solid grounds for decision making and reduces the majority of risks.

## **9. CONCLUSION**

Recurrent Neural Networks stand at the foundation of the modern-day marvels of artificial intelligence. They provide solid foundations for artificial intelligence applications to be more efficient, flexible in its accessibility and most importantly, more convenient to use. On the other hand, the results of recurrent neural network work show the real value of the information in this day and age. They show how many things can be extracted out of data and what this data can create in return. And this is incredibly inspiring.

In this study, we showed that wind energy output can be predicted from publicly available weather data with accuracy up to 80%  $R^2$  on the training range and up to 85, 5% on the unseen test data. We identified the smallest space of input variables where reported accuracy can be achieved, and provided clear trade-offs in prediction accuracy . We demonstrated that an off-the-shelf data modeling and variable selection tool can be used with mostly default settings to run the symbolic regression experiments as well as variable importance, variable contribution analysis, ensemble selection, and validation.

We are pleased that the presented framework is so simple that it can be used by literally everybody for predicting wind energy production on a smaller scale—for individual wind turbines on private farms or urban buildings, or for small wind farms. For future work, we are planning further study of the possibilities for longer-term wind energy forecasting.

## **10.FUTURE SCOPE**

Wind energy is available without any cost and it does not emit any greenhouse gases. This makes it a great source of energy production for any developing state. The field of wind energy has tremendous scope for innovation, translating to real world applications and tremendous economic opportunity.
